

Task 1: Review the Current Project Structure

- We opened the Blaze Diagnosis repository via the GitHub repository and reviewed the content inside, we have discovered the backend, frontend and API. I found the Next.js and React components and needed to install a few dependencies or rather the packages to be able to review the code for when I clone it to my local machine.

Task 2: Confirm Local Setup

- After cloning the repository, I quickly checked if there are any additional things to add and needed to install some dependencies such as the type definition for React, as it struggled to understand JSX elements. The issue remained and only documented the error for future use. It seemed like the backend and frontend seem to be not communicating correctly and made a note to check the code when we need to start debugging and testing the code itself. The other thing I have noticed is that the app does work when run locally, but everything seems to be a mess and is disorganized horrendously.

Task 3: Review the MVP Backlog

- I have seen that the MVP stories mainly cover each individual page they want, for instance, the login page, part order page, etc. I feel like I have a general idea of what each part of the code does, but I don't fully understand the entire concept behind it. We have discussed that the stories will help guide us on the different tasks that our group will need to tackle such as the frontend and backend aspects, like for instance myself and Lerato might be able to tackle the log in page, the part order page, etc and Justin and CJ might handle the backend and the API. Together we bring everything we have done to complete the connection needed and make the application look more appealing than it currently does.

Task 4: Create or Improve Documentation

- One thing I can list is the fact that some areas have placeholder of some kind and some syntax in the code is correct but just needs some fine tuning such as the modules that do not have their names in the code to properly use them, it's like calling a function that doesn't exist elsewhere in the code. Some other thing I have noticed is that we most likely, given how small our group is, need to split the debugging and testing amongst ourselves, to be able to complete the application within the given deadline we have; this month.

Task 5: Frontend Starter Task

- The one page doesn't have an import statement for the Tailwind CSS, so we might need to just add that to make it recognise the Tailwind CSS. Also, another page uses a deprecated code snippet and need to adjust that accordingly, I believe it was the node in the tsconfig.json file. A lot of the code needs certain dependencies still, so hopefully when we start tackling the code and test it, we might have more answers on how we can make this application work.
